

CATOFIN® Dehydrogenation

Overview

The CATOFIN® dehydrogenation process is a reliable, proven route for the production of isobutylene, n-butenes or propylene from isobutane, n-butane or propane respectively. Lummus Technology has exclusive worldwide licensing rights to the technology.

A total of 27 C₃ CATOFIN units have been licensed for production of propylene and 17 iC₄ CATOFIN units for the production of isobutylene.

Lummus Technology has been awarded three units to co-process mixed feedstock. Two units produce propylene and isobutylene (one of these units is the largest on purpose paraffin dehydrogenation unit in the world) as products while the other unit will produce isobutylene and normal butenes.

The CATOFIN process uses fixed-bed reactors with a catalyst and operating conditions that are selected to optimize the complex relationship among conversion, selectivity and energy consumption. The overall selectivity of isobutane to isobutylene via the CATOFIN process is greater than 90 wt% and the selectivity of propane to propylene is greater than 88 wt%. On-stream efficiencies of 98+%, excluding turnarounds of two to three weeks every three years for catalyst change, are routinely achieved.

The following information focuses on the dehydrogenation of propane to propylene.

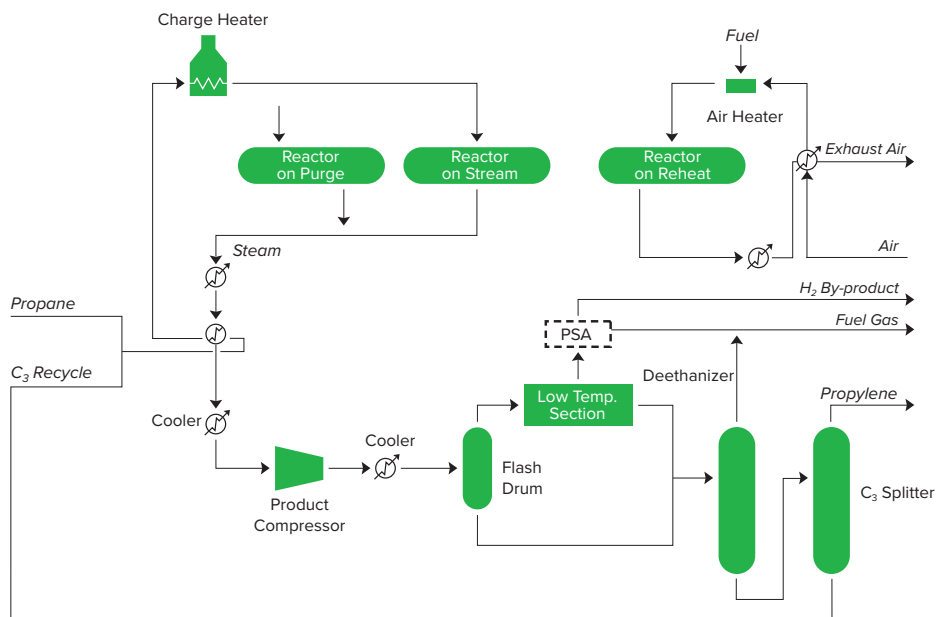

Advantages

Process Features	Process Benefits
High per pass conversion (48-53%) and high catalyst selectivity	Lower investment and operating costs
Single train capability in excess of 900,000 MTA of propylene	Economy of scale
No hydrogen recirculation or dilution steam	Lower investment and operating costs
Fixed bed reactors	Reliable and robust operation with high on-stream factor
No catalyst losses	Environmentally sound design

Performance Characteristics (Propane Dehydrogenation)

Typical Feedstocks	mol %	Product	
Propane	95 min	Propylene	99.6 mol% min
Ethane	2.5 max	Propane	0.5 mol% max
Butane +	2.5 max	Ethylene + Ethane	100 mol ppm max
Sulfur	10 wt ppm max	MAPD	10 mol ppm max
		Carbon Oxides	5 mol ppm max

Process Flow Diagram

The diagram shown is for the production of propylene. A deoiler is also included to reject a small amount of C_4 s and heavier material. For isobutylene production, the deethanizer and C_3 splitter are replaced by a depropanizer. For n -butane to n -butenes, the reactor effluent is cooled by a quench oil system and n -butane is recycled from the downstream alkylation unit.

Process Description

CATOFIN dehydrogenation is a continuous process with cyclic reactor operation in which multiple reactors go through a controlled sequence of reaction and reheat/regeneration. During the hydrocarbon processing step, fresh feed and recycle feed (typically from an MTBE synthesis unit for isobutane dehydrogenation or C_3 splitter bottoms for propane dehydrogenation) are vaporized by exchange with various process streams and then raised to reaction temperature in the charge heater. The reactor effluent is routed through a high pressure steam generator, feed-effluent exchanger and trim cooler to the compressor.

The compressor discharge is cooled, dried and routed to the low temperature recovery section to reject light ends. The low temperature section

offgas, which is a hydrogen-rich gas, can be sent to a Pressure Swing Adsorption (PSA) unit to purify the hydrogen.

Recovered liquids from the low temperature recovery section, along with the effluent flash drum liquid, are fed to distillation facilities and/or an MTBE synthesis unit for product recovery.

The reactor temperature drops during the reaction step due to the endothermic reactions. Ancillary equipment is required for the reheat/regeneration steps, which are necessary to prepare the off-line reactors for their next reaction phase. During the reheat step, any carbon deposited on the catalyst is also burned off. The entire reactor sequence is completely automated and thus requires no operator input for the cyclic operation.
